

# Rare decays in the beauty, charm and strange sector

Marcin Chrzaszcz  
mchrzasz@cern.ch

FPCP, Hyderabad  
14-18 July 2018

## 1. Beauty decays

- $\Lambda_b \rightarrow \Lambda \mu \mu$
- $\bar{B}_s^0 \rightarrow K^* \mu \mu$
- $B_{(s)} \rightarrow e \mu$
- $B \rightarrow K^* e \mu$ .

## 2. Charm decays

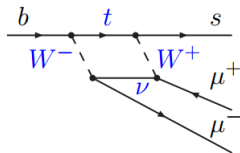

- $\Lambda_c \rightarrow p \mu \mu$
- $D \rightarrow h h \mu \mu$

## 3. Strange decays

- $K_S^0 \rightarrow \mu \mu$
- $\Sigma \rightarrow p \mu \mu$

# Why rare decays?

- The SM allows only charged interactions to change flavour.
  - Other interactions are flavour conserving.
- One can escape this constraint and produce  $b \rightarrow s$  and  $b \rightarrow d$  at loop level.
  - These kinds of processes are suppressed in the SM  $\rightarrow$  Rare decays.
  - New Physics can enter in the loops.

- Excellent Impact Parameter (IP) resolution ( $20 \mu\text{m}$ ).  
 ⇒ Identify secondary vertices from heavy flavour decays
- Proper time resolution  $\sim 40 - 50 \text{ fs}$ .  
 ⇒ Good separation of primary and secondary vertices.
- Excellent momentum ( $\delta p/p \sim 0.5 - 1.0\%$ ) and inv. mass resolution.  
 ⇒ Low combinatorial background.

- Excellent Muon identification  $\epsilon_{\mu \rightarrow \mu} \sim 97\%$ ,  $\epsilon_{\pi \rightarrow \mu} \sim 1 - 3\%$
- Good  $K - \pi$  separation via RICH detectors,  $\epsilon_{K \rightarrow K} \sim 95\%$ ,  
 $\epsilon_{\pi \rightarrow K} \sim 5\%$ .  
 $\Rightarrow$  Reject peaking backgrounds.
- High trigger efficiencies, low momentum thresholds.  
 $B \rightarrow J/\psi X$ : Trigger  $\sim 90\%$ .

# Rare beauty decays

## $b \rightarrow sll$ family

- $B \rightarrow K^* \mu \mu$
- $B_s^0 \rightarrow \phi \mu \mu$
- $\Lambda_b \rightarrow p K \mu \mu$
- LUV:  $R_K, R_{K^*}$

⇒ Too many results to be covered  
in one talk! Please see  
A. Oyanguren's talk for more!

## $b \rightarrow s\gamma$ family

- $B \rightarrow J/\psi \gamma$
- $B \rightarrow K \pi \pi \gamma$

## $b \rightarrow dll$ family

- $B \rightarrow \pi \pi \mu \mu$
- $\bar{B}_s^0 \rightarrow K^* \mu \mu$
- $\Lambda_b \rightarrow p \pi \mu \mu$

## Purely leptonic family

- $B \rightarrow ll$
- LFV:  $B \rightarrow ll'$
- LFV in  $\tau$

- $\Rightarrow b \rightarrow s \mu \mu$  in baryon sector.
- $\Rightarrow$  Because of spin 1/2 nature of the baryon there the system has to be described by 5 angles: [1710.00746](#)
- $\Rightarrow$  Impossible to perform a likelihood fit. Need to use moments:

$$M_i = \frac{3}{32\pi^2} \int \sum_{i=1}^{34} K_i(q^2) f(\vec{\Omega}) d\vec{\Omega}$$

- $\Rightarrow$  In total we have 34 observables!

- ⇒ Update with  $5 \text{ fb}^{-1}$ .
- ⇒ 610 events observed at high  $q^2$ .
- ⇒ Angular efficiency modelled in 6D.

⇒ The results:

## $b \rightarrow d$ transitions

- ⇒ The  $b \rightarrow d$  is further suppressed by  $|V_{td}|/|V_{ts}| \rightarrow \mathcal{B} \sim \mathcal{O}(10^{-8})$ .
- ⇒ Already lots of results in Run1:

[JHEP 10 (2015) 034]

[PHYS. LETT. B743 (2015) 46]

[JHEP 04 (2017) 029]

- ⇒ The ratio between the  $b \rightarrow s$  and  $b \rightarrow d$  can be used to determine some CKM elements:

$$\frac{\mathcal{B}(B \rightarrow \pi\mu\mu)}{\mathcal{B}(B \rightarrow K\mu\mu)} \sim |V_{td}/V_{ts}| = 0.20 \pm 0.02$$

- ⇒ Large improvements expected in Run2.

- ⇒ 4.6 fb<sup>-1</sup> of data!
- ⇒ Analysis in 4 bins of NN response.
- ⇒ Signal yield determined from a simultaneous fit to the NN response bins.
- ⇒ Normalized to  $B \rightarrow K^* J/\psi$ .
- ⇒ First evidence with 3.4  $\sigma$ .
- ⇒ The measured branching fraction:

$$\mathcal{B}(\bar{B}_s^0 \rightarrow K^* \mu \mu) = (2.9 \pm 1.0(\text{stat}) \pm 0.2(\text{syst}) \pm 0.3(\text{norm})) \times 10^{-8}$$

- ⇒ For now consistent with SM predictions arXiv:1803.05876

- ⇒ 4.6 fb<sup>-1</sup> of data!
- ⇒ Analysis in 4 bins of NN response.
- ⇒ Signal yield determined from a simultaneous fit to the NN response bins.
- ⇒ Normalized to  $B \rightarrow K^* J/\psi$ .
- ⇒ First evidence with 3.4  $\sigma$ .
- ⇒ The measured branching fraction:

$$\mathcal{B}(\bar{B}_s^0 \rightarrow K^* \mu \mu) = (2.9 \pm 1.0(\text{stat}) \pm 0.2(\text{syst}) \pm 0.3(\text{norm})) \times 10^{-8}$$

- ⇒ For now consistent with SM predictions arXiv:1803.05876

Lepton Flavour Violation(LFV):

⇒ After  $\mu^-$  was discovered it was logical to think of it as an excited  $e^-$ .

- Expected:  $B(\mu \rightarrow e\gamma) \approx 10^{-4}$
- Unless another  $\nu$ , in intermediate vector boson loop cancels.

I.I.Rabi:

"Who ordered that?"

- Up to this day charged LFV is being searched for in various decay modes.
  - LFV was already found in neutrino sector.
- ⇒ Anomalies may suggest connections between LUV and LFV.

$$\mathcal{B}(B \rightarrow Ke\mu) \sim 3 \cdot 10^{-8} \left( \frac{1 - R_K}{0.23} \right)$$

$$\mathcal{B}(B \rightarrow K\mu\tau) \sim 2 \cdot 10^{-8} \left( \frac{1 - R_K}{0.23} \right)$$

$$\frac{\mathcal{B}(B_s^0 \rightarrow e\mu)}{\mathcal{B}(B_s^0 \rightarrow \mu\mu)} \sim 0.01 \left( \frac{1 - R_K}{0.23} \right)$$

$$\frac{\mathcal{B}(B_s^0 \rightarrow \tau\mu)}{\mathcal{B}(B_s^0 \rightarrow \mu\mu)} \sim 4 \left( \frac{1 - R_K}{0.23} \right)$$

$$B_{(s)} \rightarrow e\mu$$

- ⇒ Need to deal with bremsstrahlung: different efficiency and mass shapes.
- ⇒ Fit performed separately in bremsstrahlung categories.
- ⇒ Primary background:  $B \rightarrow hh$ :

- ⇒ Estimated with the data driven method to be  $< 6$  events.

$$B_{(s)} \rightarrow e\mu$$

⇒ With  $3 \text{ fb}^{-1}$  data.

⇒ Fit the  $m_{e\mu}$  mass and calculate  $\text{CL}_s$ .

$$\mathcal{B}(B^0 \rightarrow e^\pm \mu^\mp) < 1.3(1.0) \cdot 10^{-8}$$

$$\mathcal{B}(B_s^0 \rightarrow e^\pm \mu^\mp) < 6.3(5.4) \cdot 10^{-9}$$

if light eigenstate dominates

$$\mathcal{B}(B_s^0 \rightarrow e^\pm \mu^\mp) < 7.2(6.0) \cdot 10^{-9}$$

if heavy eigenstate dominates

$B \rightarrow K^* e \mu$

[Belle, arxiv::1807.03267]

⇒ Fit to  $M_{bc}$ :

$$M_{bc} = \sqrt{(E_{beam})^2 - (p_B)^2}$$

⇒ No statistically significant events observed, upper limits set

⇒ The best UL but order of magnitude above the LUV model predictions.

Upper limit at 90% CL.

$$\Lambda_c \rightarrow p\mu\mu$$

⇒ SM predictions:

$$\mathcal{O}(10^{-8})$$

⇒ Long distance effects:

$$\mathcal{O}(10^{-6})$$

⇒ Previous measurement done by Babar:

$$\text{Br}(\Lambda_c^+ \rightarrow p\mu^+\mu^-) < 4.4 \cdot 10^{-5} \text{ at } 90\% \text{ CL}$$

LHCb analysis with  $3 \text{ fb}^{-1}$

- ⇒ Blind analysis with the normalization to the  $\Lambda_c \rightarrow p\phi(\mu\mu)$ .
- ⇒ BDT to reduce combinatorial background.
- ⇒ The dominant background:  $\Lambda_c \rightarrow p\pi\pi$ :  $2.0 \pm 1.1$  events

Analysis performed in 3 mass windows:

- $\phi$  region:  $m_{\mu\mu} \in [985, 1055] \text{ MeV}/c^2$
- $\omega$  region:  $m_{\mu\mu} \in [759, 805] \text{ MeV}/c^2$
- nonresonant: rest of phase-space.

$$\Lambda_c \rightarrow p\mu\mu$$

⇒ It's the first observation of  $\Lambda_c \rightarrow p\mu\mu$  in the  $\omega$  region, with  $5.0\sigma$  significance.

⇒ The corresponding branching fraction reads:

$$\mathcal{B}(\Lambda_c \rightarrow p\omega) = (9.4 \pm 3.2 \pm 1.0 \pm 2.0) \cdot 10^{-4}$$

⇒ No significant excess observed in the nonresonant region:

$$\mathcal{B}(\Lambda_c \rightarrow p\mu\mu) < 7.7(9.6) \times 10^{-8}$$

⇒ Improving BaBar result by 3 orders of magnitude!

# $D \rightarrow hh\mu\mu$

[PHYS. REV. LETT. 119, 181805 (2017)]

⇒ First observation with  $2 \text{ fb}^{-1}$  of data!

⇒ Dominated by long distance contributions.

⇒ Normalized to  $D \rightarrow K\pi[\mu\mu]_{\omega/\rho}$

⇒ LHCb has measured the branching fractions:

$$\mathcal{B}(D \rightarrow \pi\pi\mu\mu) = (9.64 \pm 0.48 \pm 0.51 \pm 0.97) \cdot 10^{-7}$$

$$\mathcal{B}(D \rightarrow KK\mu\mu) = (1.54 \pm 0.27 \pm 0.09 \pm 0.16) \cdot 10^{-7}$$

⇒ The challenge is to disentangle the SD and LD.

⇒ Angular observables can help:

$$A_{FB} = \frac{\Gamma(\cos\theta_\mu > 0) - \Gamma(\cos\theta_\mu < 0)}{\Gamma(\cos\theta_\mu > 0) + \Gamma(\cos\theta_\mu < 0)}$$

$$A_{2\phi} = \frac{\Gamma(\sin 2\phi > 0) - \Gamma(\sin 2\phi < 0)}{\Gamma(\sin 2\phi > 0) + \Gamma(\sin 2\phi < 0)}$$

$$A_{CP} = \frac{\Gamma(D \rightarrow hh\mu\mu) - \Gamma(\bar{D} \rightarrow hh\mu\mu)}{\Gamma(D \rightarrow hh\mu\mu) + \Gamma(\bar{D} \rightarrow hh\mu\mu)}$$

Analysis with  $5 \text{ fb}^{-1}$ .

See M. Gersabeck talk for more details!

⇒ Need to perform a 4D acceptance correction.

⇒ BDT technique used to determine it.

⇒ Yields done by a weighted likelihood fit.

All observables consistent with 0!

$$K_S^0 \rightarrow \mu\mu$$

⇒  $pp$  collisions create enormous amount of strange mesons.

⇒ Can be used to search for  $K_S^0 \rightarrow \mu\mu$ .

⇒ SM prediction:

$$\text{Br}(K_S^0 \rightarrow \mu\mu) = (5.0 \pm 1.5) \times 10^{-12}$$

⇒ Dominated by the long distance effects.

⇒ Bkg dominated by  $K_S^0 \rightarrow \pi\pi$ .

⇒ No significant enhancement of signal has been observed and UL was set:

$$\text{Br}(K_S^0 \rightarrow \mu\mu) < 0.8(1.0) \times 10^{-9} \text{ at } 90(95)\% \text{ CL}$$

$$\Sigma \rightarrow p\mu\mu$$

$\Rightarrow \Sigma \rightarrow p\mu\mu$  is a  $s \rightarrow d$  transition, which in SM are dominated by LD:  $\mathcal{O}(10^{-8})$ .

$\Rightarrow$  Previously HyperCP collaboration reported evidence of this decay:  
 $\mathcal{B}(\Sigma \rightarrow p\mu\mu) = (8.6_{-5.4}^{+6.6} \pm 5.5) \cdot 10^{-8}$  [Phys Rev Lett 94 021801, 2005]

$\Rightarrow$  Calibrated with  $K \rightarrow \pi\pi\pi$ :  
 resolution of  $4.28 \text{ MeV}/c^2$ .

Used  $3 \text{ fb}^{-1}$  of data.

⇒ Normalize to  $\Sigma \rightarrow p\gamma$ .

⇒ Evidence with  $4.1 \sigma$  significance.

⇒ Branching fraction measured:

$$\mathcal{B}(\Sigma \rightarrow p\mu\mu) = \left(2.2_{-1.3}^{+1.8}\right) \cdot 10^{-8}$$

# Summary

- ⇒ FCNC processes provide powerful constraints on extensions of the SM.
- ⇒ Large  $b\bar{b}$  cross-section provides a large sample of "rare" decay processes.
- ⇒ More results being updated with Run2 data.

- ⇒ Stay tuned for more results!
