FITS

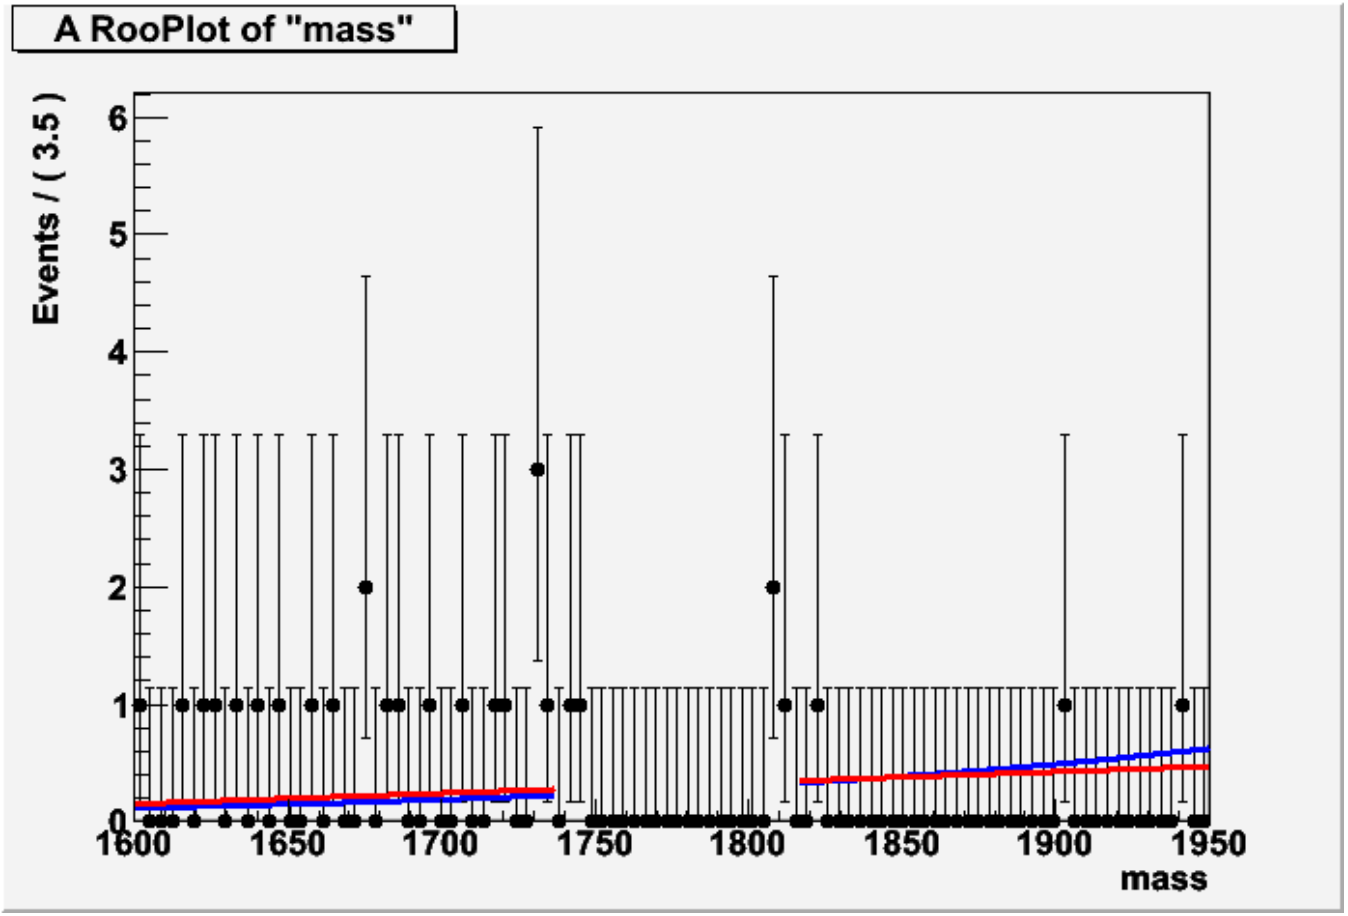
Marc sugestions:

1. Check with different strategies (RooFit::Strategy(4), etc.)
2. Change the mass window and see what happens. Mark said that if the fit will still be rising you have to prove, by changing the window get the rising fit and compare the expected number of events. If they don't change much it's ok.

1st Point

I checked all possible strategies, with different ranges(even 100 times to big). The fit is stable as hell =)

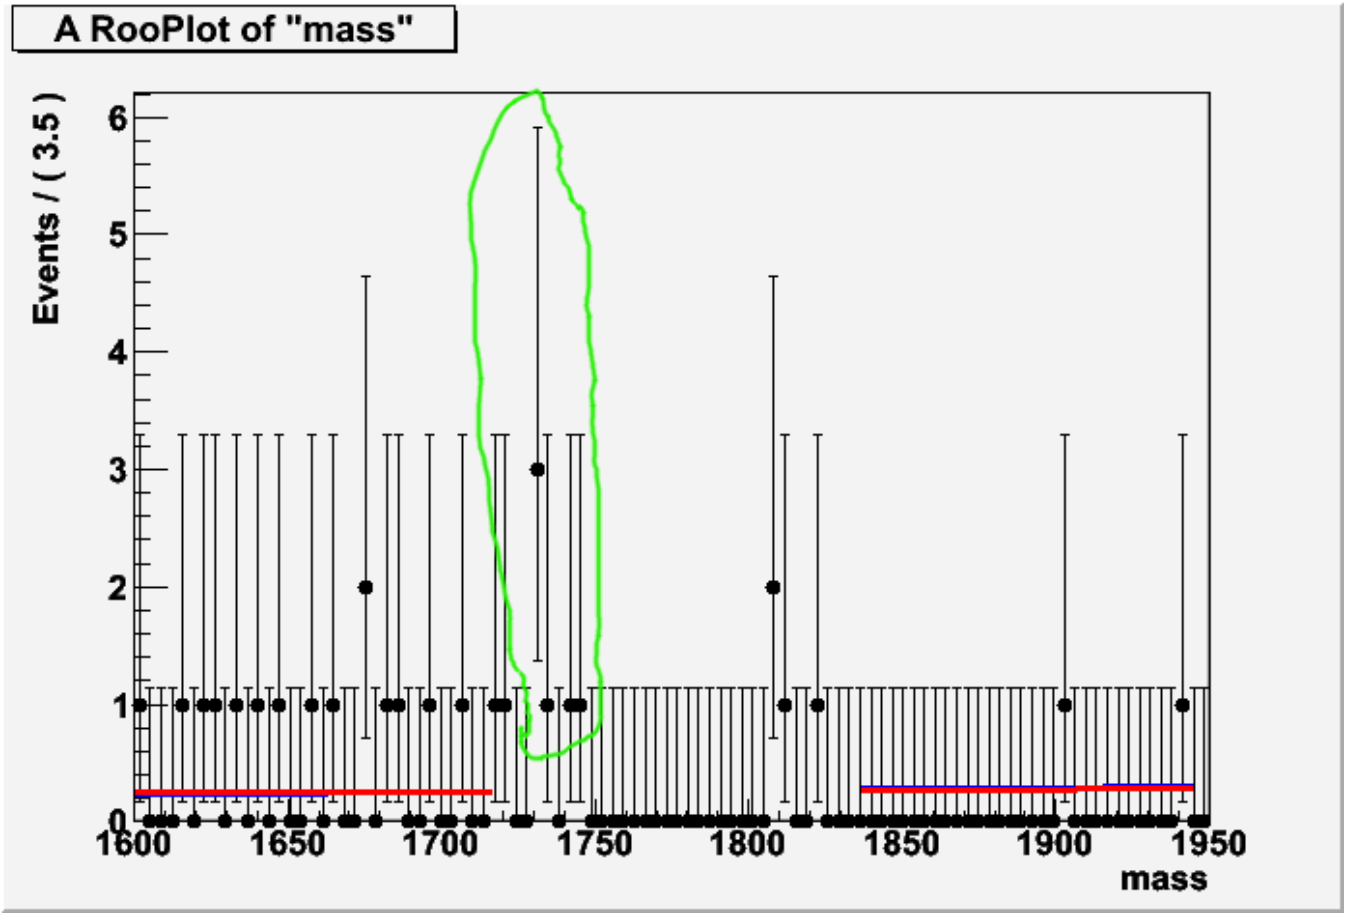
FITS



Standard fit

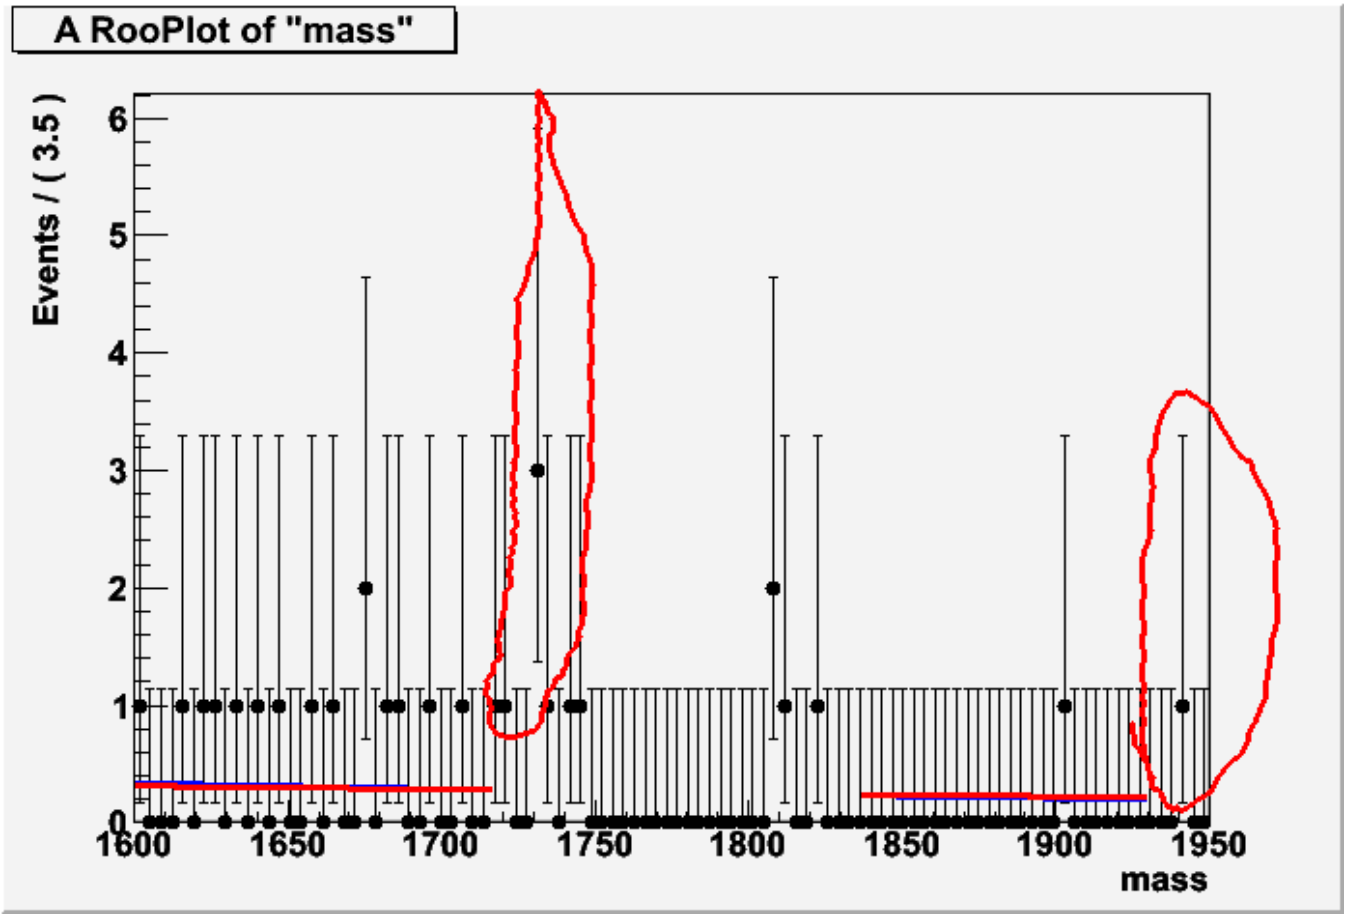
Not changed mass window

FITS



Different mass window

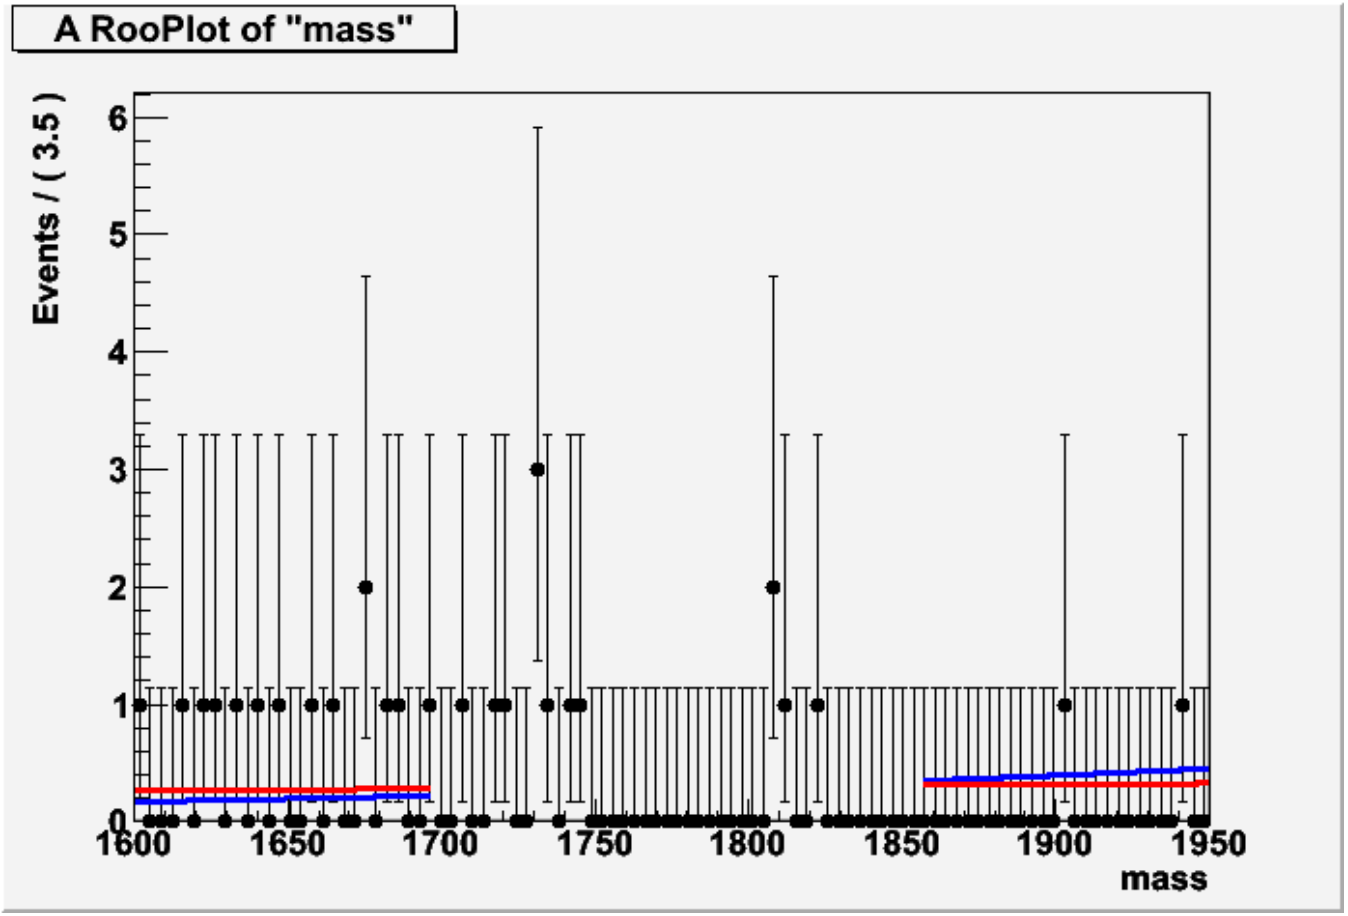
Throwing away only one marked point gives flat distribution.



Different mass window

Throwing away more point gives us droping distributions.

FITS



Different mass window

$80 MeV$ Mass window.

Summary

1. I tested this in every way I could.
2. Consulted with coleagues that are doing fits all the time(they didn't find any mistake).
3. The most important: Different mass ranges change the expected number of backgrounds eventes arround 5% so it's not relewant.

Updates on the numbers

I changed the range the from which I extrapolate the number of backgorund from the same region $(1650, 1900) \setminus (1743, 1803) MeV$

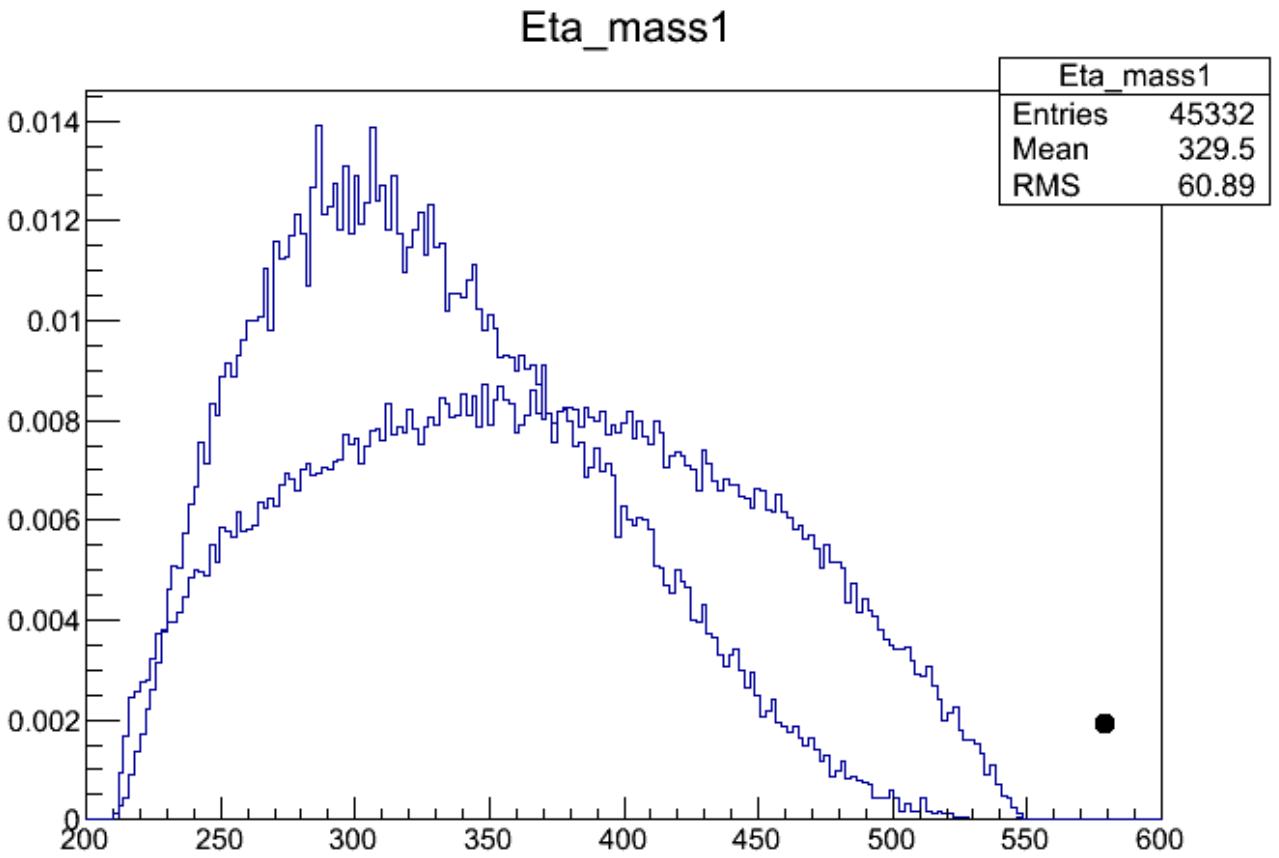
EvtGen model, without Geant



Looks much better. On on "eye test" it very similar to the one found in Martas Paper.

News about the production

1. Produced more than 400k events.
2. Started working on ntuples. Many thanks for Pauls help with software.
3. Due to limited disk space it would be good to decide soon how many events we want.

I also started working on the binning. I should have something to show on next meeting.
