$\Upsilon(4S)$ vs $\Psi(3770)$ in τ sector

Lepton Flavour Violation(LFV)

$\tau \rightarrow \mu\gamma$ at $\tau - c$ factory

QCD probe

CP Violation

$\Upsilon(4S)$ vs $\Psi(3770)$ in τ sector

1 $\tau\bar{\tau}$ cross section

- $\sigma_{\tau\bar{\tau}}(m_{\tau\bar{\tau}}) = 0.1nb$
- $\sigma_{\tau\bar{\tau}}(\Upsilon(4S)) = 0.9nb$
- $\sigma_{\tau\bar{\tau}}(\Upsilon(2S)) = 2.5nb$
- $\sigma_{\tau\bar{\tau}MAX}(4.25GeV) = 3.5nb$

$$\sigma_{\tau\bar{\tau}} = \frac{4\pi\alpha^2}{3s} \frac{3\beta - \beta^2}{2},$$

β velocity of τ

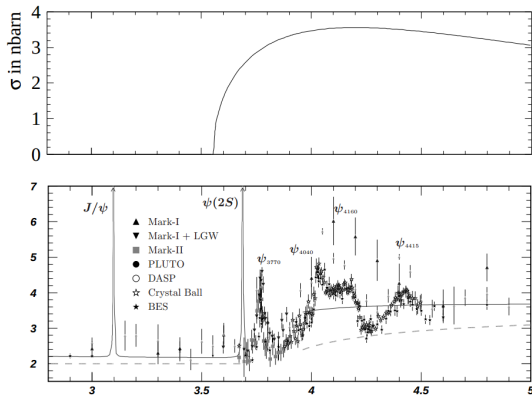

$\Upsilon(4S)$ vs $\Psi(3770)$ in τ sector

② SuperB $75ab^{-1}$:

- Number of $\tau\bar{\tau}$ produced:
 $0.9nb \times 75ab^{-1} = 6.8 \times 10^{10}$

③ $\tau - c$ factory $7.5ab^{-1}$:

- Number of $\tau\bar{\tau}$ produced:
 $3 \times 7.5ab^{-1} = 2.3 \times 10^{10}$

Current Status of LFV

1 Theoretical considerations:

- LFV predicted in many NP models(SUSY, Majorana neutrinos).
- In SM negligibly small $\mathcal{B} < 10^{-54}$ ¹.
- Any observation clear sign of NP.

2 Experimental status:

- Limits for LFV channels set by BaBar, Belle and Cleo in range of $10^{-7} - 10^{-8}$ depending on the decay channel.
- Most promising channels: $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow 3\mu$.

¹T.P Cheng, L.Li, Phys. Rev. Lett. 45 (1980) 1908

$\tau \rightarrow \mu\gamma$ at $\tau - c$ factory

SM background for $\tau \rightarrow \mu\gamma$:

- $\tau \rightarrow \mu\gamma\nu_\mu\nu_\tau$
- $\tau \rightarrow \pi\pi^0\nu_\tau$
- $\tau\tau \rightarrow \mu\nu_\mu\nu_\tau + \pi\pi^0\nu_\tau \rightarrow \mu\gamma\pi^+\gamma\mu\nu_\tau\nu_\tau$
- Initial state radiation: $e^+e^- \rightarrow \tau\bar{\tau}\gamma$
- Initial state radiation: $e^+e^- \rightarrow \mu\bar{\mu}\gamma$

ISR strongly suppress the the sensitivity in B factories.

Suppression ISR at charm threshold

E_γ FSR

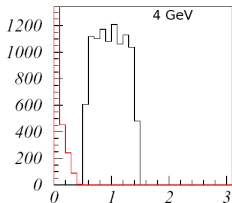

$E_{\gamma\tau} \rightarrow \mu\gamma$

ISR

vanishes

for

$E \approx 4\text{GeV}$

Expected sensitivity for $\tau \rightarrow \mu\gamma$

From MC studies ² one can estimate the background in the $\tau \rightarrow \mu\gamma$ factory using KK2F with TAUOLA generator.

A full data set of $7.5ab^{-1}$ is sufficient to put an exclusion limit on $\tau \rightarrow \mu\gamma$ of order of 10^{-9} .

Probe QCD

- Using analytical constraints and the Operator Product Expansion one can compute ratio between hadronic and leptonic decays:

$$R_\tau \equiv \frac{\Gamma(\tau \rightarrow \nu \text{ hadrons}(\gamma))}{\Gamma(\tau \rightarrow e \nu_\tau \nu_e)} = R_{\tau,V} + R_{\tau,A} + R_{\tau,S}$$

- Which can be further divided to contributions coming from different quarks and currents:

$$R_\tau \equiv \frac{\Gamma(\tau \rightarrow \nu \text{ hadrons}(\gamma))}{\Gamma(\tau \rightarrow e \nu_\tau \nu_e)} = R_{\tau,V} + R_{\tau,A} + R_{\tau,S}$$

- Theoretical prediction can be written in a form:

$$R_{\tau,V+A} = N_c |V_{ud}|^2 S_{EW} (1 + \delta_P + \delta_{NP})^3$$

- Biggest correction comes from δ_P .

CP Violation

- CP violation in τ sector is becoming a popular subject in light that the CKM matrix cannot explain matter-antimatter asymmetry.
- Much more decay modes than in μ sector.
- Possible contributions from charge Higgs at loop level.

The most promising channel is: $\tau \rightarrow K_S \pi \nu$

- 1 SM in 3rd loops generates asymmetry.
- 2 Numerical studies showed that NP can contribute in 1%
- 3 Expected sensitivity with full data set is expected to be of the order of 0.01%
