

$B \rightarrow K_{\tau\tau}$ search in $B \rightarrow K_{\mu\mu}$ decays

Sascha Liechti

Supervisors: Nicola Serra, Patrick Owen

University of Zurich - LHCb group

Overview

1. Decay
2. Search
 - Theory
 - Pdf and its parts
 - Where we are now
3. Outlook

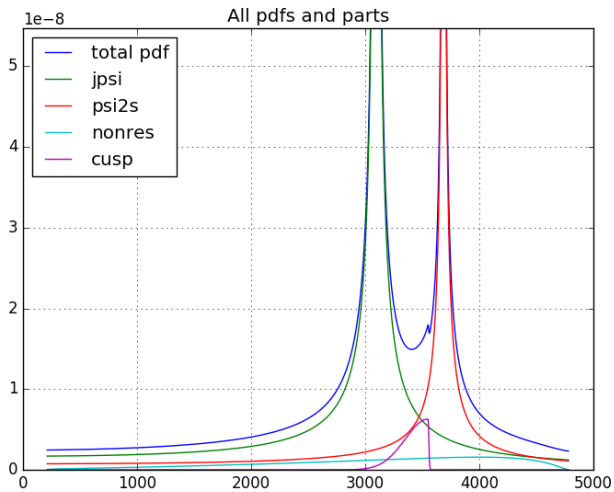

All results and plots are very preliminary

Decay

- Anomalies gave rise to new search for possible lepton flavor universality violation
 - Different couplings to leptons of different generations
 - ▷ Most to τ , least to e
 - ▷ How can we observe different generations at once?

- According to SM the τ contribution should not be visible in the dimuon spectrum
 - Dependent on Wilson coefficients ($C7$), $C9$, $C10$
 - ▷ Some SUSY models predict an amplification of the τ contribution:
 - ▷ Amplification due to new channel
 - ▷ Amplification factor: **10 - 1000**
- ⇒ τ contribution should become visible
- Cusp like shape in between J/ψ and $\psi(2S)$ resonances
 - At the moment still a bifurkated gaussian
(shape will slightly change once we get the exact shape)

Extremely sensitive to cusp amplitude

Cusp amplitude: $6 \cdot 10^{-7}$

Cusp amplitude: $4 \cdot 10^{-7}$

What can we do for now:

- Generate toys (equivalent size of data taken in run I and II)
- Running model of the dimuon spectrum and the relevant contributions for this search
 - Rare nonresonant
 - J/ψ
 - $\psi(2S)$
 - *Cusp*
 - Will be added in the future: cc , $B \rightarrow DDK$, DD^*K , D^*D^*K
- Binned fit pdf to the data and calculate likelihood

Next steps:

- Integrate true shape of the cusp
- Add cc , $B \rightarrow DDK$, DD^*K , D^*D^*K
 - ▷ Only $B \rightarrow DD^*K$ nonresonant
- Implement additional crosschecks
- Analyze resolution
- Low energy regime fit:
 - ▷ Improve sensitivity on c part and τ tail by including a constraint from low q^2
